# Adapting some statistical methods to analyze TDS in drinking water 

Saif Adnan Salman ${ }^{1}$, Ahlam Ahmed Juma ${ }^{2}$<br>${ }^{1}$ Ministry of Education<br>${ }^{2}$ College of Arts, University of Baghdad

#### Abstract

In this study, numerous statistical models were used including the Box-Jenkins models with several stages to build and forecasting the best model in the analysis of time series. Modern methods in time series analysis including fuzzy logic and fuzzy sets, have appeared as the most important alternatives to classical statistical methods. They have a mechanical ability to find solutions because they do not require the availability of classical model conditions, which are difficult to achieve in most cases. This paper aims to find the best method to analyze the behavior of pollution rates by studying Box-Jenkins and high order fuzzy time series methods. Then, an adaptation has conducted between the two methods as a proposed procedure on chemical examined data for total dissolved solids in drinking water for Baghdad city. The data are recorded from January 2004 to December 2018. These methods are compared in details through statistical criteria RMSE, MAE, MAPE.

Keywords: ARIMA, high order fuzzy, TMF, PSO, prediction, criterion.

## 1. Introduction

Statistics science has prioritized the forecasting of time series for foreseeing the future through prediction theory and methods of forecasting techniques. The idea of documenting the historical data for phenomena in all fields using these data in forecasting is one of the most important statistical bases. A lot of statistical techniques have been used in this field, such as regression analysis, Box-Jenkins models etc., which were prevalent. Due to the great interest in the field of inaccuracies existing in various fields, the fuzzy has emerged to mimic human thinking, which depends on contrastive degrees. Fuzzy groups have found successful applications in many fields.
Fuzzy logic is a technique with the ability to find solutions for various scientific and human problems. The most important modern techniques for the application of this logic is the idea of fuzzy time series. It was proposed by the researchers' Song and Chissom in 1993 as an alternative to classical methods, which gives effective results as compared with classical statistical techniques [1].
The goal of the paper is to analyze the behavior of pollution rates in drinking water for Baghdad city by using the Box-Jenkins and high order fuzzy time series methods. An adaptation the two methods as a modified technique was employed to improve the adequacy of the model. It has taken a series of monthly chemical examinations for the total dissolved solids (TDS) from January 2004 to December 2018 for drinking water in Baghdad city. The best method is found in several comparative criteria based on RMSE, MAE, and MAPE.

## 2. Methodology

### 2.1. Box-Jenkins method

The autoregressive model (AR) represents the correlation of the current observations of the time series with previous observations of the same series and can be written as follows:

$$
\begin{equation*}
Z_{t}=\phi_{1} Z_{t-1}+\phi_{2} Z_{t-2}+\ldots+\phi_{p} Z_{t-p}+a_{t} \tag{1}
\end{equation*}
$$

It can be denoted as $\operatorname{AR}(\mathrm{p})$ and $p$ represents the model's order. Accordingly, $Z$ represents the series observations and $\phi$ represents the parameters of the model.
The moving average model (MA) is a correlation of the current observations of the time series with the same series error as previous observations and the general equation:
$Z_{t}=a_{t}-\theta_{1} a_{t-1}-\theta_{2} a_{t-2}-\ldots-\theta_{q} a_{t-q}$
It is denoted as MA(q) and q represents the model's order. Accordingly, $\theta$ represents the parameters of the model.
The mixed model autoregressive-moving average denoted as $\operatorname{ARMA}(p, q)$ is the correlation of the current time series values with previous values of the same series. Also, it includes the correlation of the series values with the same series error of previous observations as follows:

$$
\begin{equation*}
Z_{t}-\phi_{1} Z_{t-1}-\phi_{2} Z_{t-2}-\ldots-\phi_{p} Z_{t-p}=a_{t}-\theta_{1} a_{t-1}-\theta_{2} a_{t-2}-\ldots-\theta_{q} a_{t-q} \tag{3}
\end{equation*}
$$

Where ( $p, q$ ) stands for the model order, and the model above represents the non-seasonal part or the so-called regular part for the time series.
Most studies have proven that autoregressive integrated moving average models (ARIMA) have superiority in all applied fields in model identification and time series prediction. For these models transformation, the time series has the stationarity feature. It is realized by taking a number of differences $d$ for non-stationary time series where the degree of differences d is given, and $w_{t}=\nabla^{d} Z_{t}$ for transforming it into a stationary series. The ARIMA(p, d, q) model can be written as [2, 3]:

$$
\left.\begin{array}{cc}
\phi_{p}(B) w_{t}=\phi_{p}(B) \nabla^{d} Z_{t}=\theta_{q}(B) a_{t} & , a_{t} \sim W N\left(0, \sigma^{2}\right)  \tag{4}\\
\text { OR } \quad \phi_{p}(B)(1-B)^{d} Z_{t}=\theta_{q}(B) a_{t} & , a_{t} \sim W N\left(0, \sigma^{2}\right)
\end{array}\right]
$$

### 2.2. Building the Box-Jenkins method

The Box-Jenkins (B-J) method is used to represent and analyse stationary or non-stationary time series, for seasonal and non-seasonal types. It can predict future values of the phenomenon by applying models of this method in the process of building the model of the time series. It includes identification the series and determines the appropriate model using some suitable criteria for this stage with estimation and prediction processes [2, 4].

Figure1. Box-Jenkins model building stages algorithm

The Box Jenkins methodology is one of the most important methods for predicting time series. It was presented by researchers Box \& Jenkins in 1970, as one of the most used methods in the analysis of the time series. This method is based on several stages:

- Stationary check stage of time series and application of transformation conversions needed to make them stationary.
- Determination of the appropriate model within the ARIMA models.
- Estimation of selected model parameters by one of the estimation methods.
- Diagnosis checking to investigate its feasibility for the time series.
- Forecasting using the selected model.

Figure 1 illustrates the model-building algorithm for B-J method [5].

### 2.3. Statistical criteria

A number of statistical criteria is used to differentiate between time series models. Then, it has selected the model order that corresponds to the lowest value for each criterion, including [4, 6]:

## - Root square for mean square error

The mathematical equation of root square for mean square error denoted by RMSE is:

$$
\begin{equation*}
R M S E=\sqrt{\frac{\sum \hat{a}_{t}^{2}}{n}}=\sqrt{M S E} \quad, \hat{a}_{t}^{2}=\left(Z_{t}-\hat{Z}_{t}\right)^{2} \tag{5}
\end{equation*}
$$

Where,
MSE represent mean square error.

- The mean absolute error (MAE)

The mean absolute error can be written as:

$$
\begin{equation*}
M A E=\frac{\sum\left|\hat{a}_{t}\right|}{n} \quad, \hat{a}_{t}=Z_{t}-\hat{Z}_{t} \tag{6}
\end{equation*}
$$

## - Mean absolute percentage error

The mathematical equation for mean absolute percentage error (MAPE) is determined by:
$M A P E=\frac{\sum\left(\left|\hat{a}_{t}\right| / Z_{t}\right)}{n} \times 100$

### 2.4. Fuzzy time series

Fuzzy time series are modern methods of prediction that were proposed by Song and Chissom in 1993 through their research reported [7]. They introduced the definition of fuzzy time series models and their most important features. Some definitions for fuzzy time series models are based on the following [8, 9]:

- Definition (1): Fuzzy time series

If we had $Z(t)$ and $t=(\ldots, 0,1,2,3, \ldots$.$) as sets of real number, a universe of discourse can be defined with$ the fuzzy sets $f_{i}(t), i=(1,2,3, \ldots)$. However, $F(t)$ is a time series defined within the specified period $f_{i}(t)$
.In this case, $F(t)$ is a fuzzy time series on $Z(t)$ and $f_{i}(t), i=(1,2,3, \ldots)$ which are linguistic values of the linguistic variable are $F(t)$.

- Definition (2): To establish fuzzy logic relationship (FLR), suppose that $F(t-1)=A i$. So, the relationship between the two consecutive observations $F(t)$ and $F(t-1)$ gives us a fuzzy logic relationship (FLR) $A_{i} \rightarrow A_{j}$.
The fuzzy logic relationships can be written in the form that each fuzzy relationship has the same fuzzy variables on the left $(A i)$. For example, if we have the two relationships:

$$
A_{i} \rightarrow A_{j 1}, A_{i} \rightarrow A_{j 2}
$$

So, it's written as:
$A_{i} \rightarrow A_{j 1}, A_{j 2}$

- Definition (3): If we suppose that $F(t)$ is a result of $F(t-1), F(t-2), \ldots, F(t-n)$

So, the fuzzy logic relationship can be written as follows:
$F(t-2), F(t-1), \ldots, \rightarrow F(t)$
This term is called the fuzzy time series prediction model of ( $n$ ) degree so that $n \geq 2$. Several fuzzy time series models were projected in recent years that have manipulated many problems for different fields, including the high order fuzzy time series model.

### 2.5. High order fuzzy time series model

The high order fuzzy time series prediction model requires a number of steps to obtain predictive values. The process of predicting by using this model has mainly divided into dual parts of fuzzification and defuzzification [10].
The algorithm fuzzification depends on the generation of a time series of trapezoid fuzzy sets [11] for the original time series data and formation the relationships between the original data and the generated fuzzy aggregated. The fuzzification data process can be divided into six main steps [12,13,14]:
I. Arrangement of time series data in ascending order.
II. Calculating the average distance which denoted by (AD) between any two consecutive values $\left(x_{p}\right)$ in the resulting data from the previous step as follows:

$$
\begin{equation*}
A D\left(x_{i}, \ldots, x_{n}\right)=\frac{1}{n-1} \sum_{i=1}^{n-1}\left|x_{p(i)}-x_{p(i+1)}\right| \tag{8}
\end{equation*}
$$

and though $x_{p(i)} \leq x_{p(i+1)}$.
A standard deviation (SD) of the AD is calculated by:
$S D_{A D}=\sqrt{\frac{1}{n} \sum_{i=1}^{n}\left(x_{i}-A D\right)^{2}}$
III. Removing the AD values that lie outside the limits of the following defined period:
$A D-S D \leq m \leq A D+S D$
Here, $(m)$ represents the set of values that lie within this period.
IV. Calculating the average distance rate $\left(A D_{R}\right)$ by taking the average for the values specified in the previous step $(m)$.
V. Definition of the limits of the universe of discourse $(U)$ as follows:

$$
\begin{equation*}
U=\left[D_{\min }-A D_{R} \quad, \quad D_{\max }+A D_{R}\right] \tag{11}
\end{equation*}
$$

Here, $\left(D_{\min }, D_{\max }\right)$ stand for lowest and the highest values in time series data respectively.
Fuzzification of time series data has been by using trapezoidal membership function (TMF). This process requires knowing the number of fuzzy sets (L) that must be based on $(U)$. A number of these sets have calculated by:
$L=\frac{R-A D_{R}}{2 \times A D_{R}}$
Here, $R$ is defined the domain of universe of discourse and calculated as a follows:
$R=U B-L B$
The $(U B, L B)$ are the upper and lower limit that were defined in equation (11).
The second section of this model is the process of defuzzification and the calculation of predictive values. To know how to calculate the output of the defuzzification process, use the defuzzification operator that defined with the following equation:
$X_{t}=\sum_{i=1}^{n} x_{t-i} \cdot w_{i}$
Namely, $w_{i} \in[0,1]$ and $\left(x_{t-i}\right)$ is the actual value for the time series in time $(t-i)$. Accordingly, L is depending on the range of time series. Assuming that $(\mathrm{L}=2)$, the defuzzification factor can be computed by:
$X_{t}=\left(x_{t-1} \cdot w_{1}\right)+\left(x_{t-2} \cdot w_{2}\right)$

The defuzzification factor $\left(X_{t}\right)$ can conclude a fuzzy logic view since weights ( $w_{i}$ ) are fuzzy relationships between the previous and subsequent values in the time series. Each of these weights $\left(w_{i}\right)$ stands for the strong point of the causal association between the input values to the series and the resulting undefined values. The strongest causal relationship is being when the weight value $\left(w_{i}\right)$ is near to (1).
The process of defuzzification can be summarized as follows:

## - Establishing fuzzy set groups

In classical fuzzy time series models [15, 16], fuzzy logic relationships can be defined after fuzzification of time series data. But, in this model, the right side of fuzzy logic relationships is undefined until weights $\left(w_{i}\right)$ are calculated. Therefore, we established the fuzzy set groups (FSGS) instead of fuzzy logic relationships by inserting fuzzy groups into arranged pairs. The aim of listing fuzzy sets in this shape is to find out if dual or more FSGS have the identical group components (fuzzy groups). Its aim is also to obtain a series of FSGS that do not contain a similar frequency for more than once in its values. FSGS items are taken from the third order to obtain a FSGS series that does not have frequencies groups.

## - Transforming groups for fuzzy set into (If) rule

The rules (If ) for fuzzy set groups FSGS can be evaluated using the following:

$$
\begin{equation*}
\operatorname{If}\left(F(t-1)=A_{i, t-1} \wedge F(t-2)=A_{i, t-2} \wedge \ldots \wedge F(t-n)=A_{i, t-n}\right) \tag{14}
\end{equation*}
$$

- Evaluating the rules of (If -then) by using particle swarm optimization

In this step we use particle swarm optimization which denoted (PSO) by using the following equation [17,18]:

$$
\begin{align*}
& v_{i+1}=w \cdot v_{1}+c_{1} r_{1}\left(\hat{x}_{i}-x_{j}\right)+c_{2} r_{2}\left(\hat{g}-x_{j}\right)  \tag{15}\\
& x_{j+1}=x_{j}+v_{i+1}
\end{align*}
$$

To obtain the necessary weights $\left(w_{i}\right)$ to calculate the value of the coefficient of defuzzification $\left(X_{i}\right)$, the coefficients of the PSO function can be determined as follows:

- The value of the weight coefficient $w$ is equal 1.4.
- The value of the velocity coefficients of elements $c_{1}, c_{2}$ equal to 2 .
- The value of $\left[-v_{\max }, v_{\max }\right]$ are defined within the interval $[-0.01,0.01]$.
- The highest and the lowest values of the function elements are defined within the interval [0,1].
- The number of the elements of the PSO function is equal 5.

It is conventional to select the values of the function's coefficients of such form as they give the best results. The best global fitness value can be expressed in terms of the square error (SE) value, which is defined according to the following equation:
SE $=[\text { Forecast }- \text { Actual }]^{2}$
The basic idea for calculating the best global fitness value is to reduce the square error between the defuzzilied value and the real value in the corresponding time series in time $(t)$. When getting to this value, the element coordinates in the PSO function, which gives the optimal value, represent the value of the weights ( $w_{i}$ ).

## - Estimating the forecasting value

After calculating the optimal weights, the prediction values have also calculated based on the evaluation of the rules (If- then) measured before in the previous step for each time series values.

### 2.6. Proposed procedure

The adaptation procedure for the Box-Jenkins series was applied using the high order fuzzy time series method as a proposed procedure to improve the adequacy of the model. This procedure was done by taking predictive data for the best ARIMA model as a new time series and processing it with a high order fuzzy time series method. The proposed procedure was compared with dual research methods used to find the best in the prediction process by some statistical criteria.

## 3. Analysis of the total dissolve solid data for drinking water

Water pollution is one of the first issues that attract the interest of researchers and specialists in the field of pollution because of the importance of water and its necessity in all biological processes. Drinking water is the basic element for the formation of communities and the emergence and prosperity of cities. Consequently, water processing is very important in daily life to obtain safe water for human health. The quality of water depends on its physical, chemical and biological properties and the extent to which humans can use it. This requires a specific approach to modify one or more of these properties.
On this basis, standard specifications for water quality have built through several examinations to determine the quality of water. The most important one, which has the total dissolved solids (TDS), had taken from drinking water in the city of Baghdad from January 2004 to December 2018. The examinations are measured in (mg/l) units. The used data and methods have been analysed according to SPSS Var.20, STATISTICA Var.7, and MATLAB 2009b programs.

### 3.1 Box-Jenkins method

One of the steps that have used in analysing any time series is to draw it to see the trend and stationarity of the series. The seasonality of the time series was tested by using the Jonckheer-Terpstra test of equal value with J$\mathrm{T}=1.104$ when p -value $=0.270$. This is not to reject the null hypothesis, and reaching that data is not seasonal at the significant level of 0.05 . Figure 2 shows that time series have a trend and non-stationary, as illustrated in Figure 3 of the two functions of autocorrelation (AC) and partial autocorrelation (PAC), which shows by drawing the functions that the series is non stationary in mean.

Figure 2. TDS data for drinking water in Baghdad city

Figure 3. AC and PAC for TDS series
A Dickey-Fuller test for data with $\mathrm{DF}=0.534$ was calculated. This value is less than the tabular value of 1.943 with a level of 0.05 . This refers that the null hypothesis is not rejected and the series is non stationary. Thus, the first differences of data were taken. Figure 4 shows the coefficients of AC and PAC. It shows the stationary in the series with $\mathrm{DF}=12.578$, which is greater than the tabular value of 1.943 at a level of 0.05 . This refers to the rejection of the null hypothesis and that the data has stationary.
Based on the stationary data, a number of combinations of statistical models have been applied. Table 1 shows the representation of models. It is clear that the model ARIMA ( $3,1,3$ ) is appropriate for the data, which corresponds to the lowest values in the following criteria: RMSE, MAE, MAPE with the significance of its parameters.

Figure 4. AC and PAC for TDS series after taking the first difference
Table 1. A number of combinations of statistical models to represent the TDS

| Criteria | RMSE | MAPE | MAE |
| :---: | :---: | :---: | :---: |
| ARIMA(0,1,1) |  | 6.938 |  |
| ARIMA(0,1,2) | 52.876 | 6.940 | 38.059 |
| ARIMA(0,1,3) | 52.814 | 7.065 | 38.657 |
| ARIMA(1,1,0) | 53.129 | 6.943 | 38.064 |
| ARIMA(1,1,1) | 53.050 | 6.884 | 37.748 |
| ARIMA(1,1,2) | 50.855 | 6.655 | 36.937 |
| ARIMA(1,1,3) | 50.880 | 6.656 | 36.942 |
| ARIMA(2,1,0) | 52.977 | 6.952 | 38.102 |
| ARIMA(2,1,1) | 53.079 | 6.897 | 37.842 |
| ARIMA(2,1,2) | 50.876 | 6.657 | 36.961 |
| ARIMA(2,1,3) | 51.006 | 6.650 | 36.924 |
| ARIMA(3,1,0) | 53.123 | 6.939 | 38.046 |
| ARIMA(3,1,1) | 53.230 | 6.900 | 37.854 |
| ARIMA(3,1,2) | 50.972 | 6.638 | 36.854 |
| ARIMA(3,1,3) | 50.277 | 6.628 | 36.830 |

The estimation of the model parameters ARIMA $(3,1,3)$ is equal to:

| $\phi_{1}=$ | $-0.536 \phi_{2}=$ | $0.195 \phi_{3}=$ | 0.724 | $\theta_{1}=$ | -0.486 |
| :--- | :---: | :---: | :---: | :---: | :---: |
| $\theta_{2}$ | $=0.470$ | $\theta_{3}=0.986$ |  |  |  |
| s.e: | 0.069 | 0.078 | 0.068 | 0.105 | 0.062 |
| sig: | 0.000 | 0.013 | 0.000 | 0.000 | 0.000 | 0.138

Accordingly, the selected model will be written in the following form:
$\left(1+0.536 B-0.195 B^{2}-0.724 B^{3}\right)(1-B) Z_{t}=\left(1+0.486 B-0.470 B^{2}-0.986 B^{3}\right) a_{t}$
To compute the accuracy of the ARIMA(3,1,3), the Q-tests for Box-Pierce and Ljung-Box were established for a series of errors in the model in the case of $\mathrm{Q}_{\mathrm{B}-\mathrm{P}}=48.775, \mathrm{Q}_{\mathrm{L}-\mathrm{B}}=50.872$. The value of $\chi^{2}$ table value based on d.f $=39$ and $\alpha=0.05$ is equal to 54.561 obviously. The null hypothesis is not rejected. This refers that the selected model is appropriate for representing the TDS data in for the period of study and that the model errors have a random characteristic. The AC and PAC coefficients for the residuals series of the model were plotted after checking their coefficients within the confidence intervals $\left\{ \pm 1.96(n)^{-\frac{1}{2}}\right\}$ with $95 \%$ confidence level, Figure 5 shows the significance of some correlation coefficients at a number of lags and equal to 5 . This is not effective as total numbers of lags equal to 45 , because there are high fluctuations and few series of errors. Thus, the errors of the model can be considered to have a white noise.

Figure 5. AC and PAC for the residual's model of the $\operatorname{ARIMA}(3,1,3)$
Fig. 6 shows the series observations and predictive values according to the selected model.

Figure 6. Observational and predictive values of the $\operatorname{ARIMA}(3,1,3)$ model for TDS series

### 3.2. High order fuzzy time series method

Monthly data for the TDS has taken in to consideration. The steps of the high order fuzzy time series model prediction method have applied through the fuzzification and defuzzification stages as follows:

## - Fuzzification stage

Time series data have been fuzzified by using the trapezoidal membership functon (TMF)in fuzzification data. It requires to know the number of fuzzy sets and the length of each interval for this sets. The following steps have been applied:

- Average distance is equal to $\mathrm{AD}=2.4246$
- Average distance rate $(\mathrm{ADR})=1.7535$
- The limits of the universe of discourse ( U$)=[362.2465,799.7535]$
- Number of fuzzy sets (n) = 124

Therefore, the fuzzy sets of series data, which are 124 fuzzy sets, can be defined by using the (TMF) as shown in Table 2.

Table 2. Fuzzy sets of the high order fuzzy model for TDS series

| Fuzzy <br> Sets | Fuzzy Numbers |  |  |  | Fuzzy Sets | Fuzzy Numbers |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{A}_{1}$ | 362.2465 | 364 | 365.7535 | 367.507 | $\mathrm{A}_{63}$ | 579.6805 | 581.434 | 583.1875 | 584.941 |
| $\mathrm{A}_{2}$ | 365.7535 | 367.507 | 369.2605 | 371.014 | $\mathrm{A}_{64}$ | 583.1875 | 584.941 | 586.6945 | 588.448 |
| $\mathrm{A}_{3}$ | 369.2605 | 371.014 | 372.7675 | 374.521 | $\mathrm{A}_{65}$ | 586.6945 | 588.448 | 590.2015 | 591.955 |
| $\mathrm{A}_{4}$ | 372.7675 | 374.521 | 376.2745 | 378.028 | $\mathrm{A}_{66}$ | 590.2015 | 591.955 | 593.7085 | 595.462 |
| $\mathrm{A}_{5}$ | 376.2745 | 378.028 | 379.7815 | 381.535 | $\mathrm{A}_{67}$ | 593.7085 | 595.462 | 597.2155 | 598.969 |
| $\mathrm{A}_{6}$ | 379.7815 | 381.535 | 383.2885 | 385.042 | $\mathrm{A}_{68}$ | 597.2155 | 598.969 | 600.7225 | 602.476 |
| $\mathrm{A}_{7}$ | 383.2885 | 385.042 | 386.7955 | 388.549 | $\mathrm{A}_{69}$ | 600.7225 | 602.476 | 604.2295 | 605.983 |
| $\mathrm{A}_{8}$ | 386.7955 | 388.549 | 390.3025 | 392.056 | $\mathrm{A}_{70}$ | 604.2295 | 605.983 | 607.7365 | 609.49 |
| $\mathrm{A}_{9}$ | 390.3025 | 392.056 | 393.8095 | 395.563 | $\mathrm{A}_{71}$ | 607.7365 | 609.49 | 611.2435 | 612.997 |
| $\mathrm{A}_{10}$ | 393.8095 | 395.563 | 397.3165 | 399.07 | $\mathrm{A}_{72}$ | 611.2435 | 612.997 | 614.7505 | 616.504 |
| $\mathrm{A}_{11}$ | 397.3165 | 399.07 | 400.8235 | 402.577 | $\mathrm{A}_{73}$ | 614.7505 | 616.504 | 618.2575 | 620.011 |
| $\mathrm{A}_{12}$ | 400.8235 | 402.577 | 404.3305 | 406.084 | $\mathrm{A}_{74}$ | 618.2575 | 620.011 | 621.7645 | 623.518 |
| $\mathrm{A}_{13}$ | 404.3305 | 406.084 | 407.8375 | 409.591 | $\mathrm{A}_{75}$ | 621.7645 | 623.518 | 625.2715 | 627.025 |

By defining the fuzzy sets, the time series data has been fuzzified by converting their observations into linguistic variables. Table 3 explains the fuzzification of data to determine the membership function for each linguistic variable. For example, it is noted that the value of the test in January 2004, which is equal to 473, lies within the interval of the linguistic variable $\mathrm{A}_{32}$. It is based on the following fuzzy numbers from Table 2: (470.9635, 472.717, 474.4705, 476.224).

Table 3. Fuzzification the data of TDS for the high order fuzzy model

| Linguistic <br> Variable | Month | Year | Linguistic Variable | Month | Year | Linguistic <br> Variable | Month | Year | Linguistic Variable | Month | Year |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{A}_{110}$ | Nov |  | $\mathrm{A}_{64}$ | Nov |  | $\mathrm{A}_{72}$ | Nov |  |  |  |  |
| $\mathrm{A}_{104}$ | Dec |  | $\mathrm{A}_{84}$ | Dec |  | $\mathrm{A}_{75}$ | Dec |  |  |  |  |

## - Defuzzification stage

This stage involves a number of steps to arrive at the prediction process. The FSGS fuzzy sets are established as in Table 4.

Table 4. FSGs for TDS series (high order fuzzy model)

| \# | FSGS | \# | FSGS | \# | FSGS | \# | FSGS | \# | FSGS |

From Table 4, it is clear that there are frequencies in some elements of fuzzy set group sets (FSGS). The group $\left\{\mathrm{A}_{39}, \mathrm{~A}_{58}\right\}$ and group $\left\{\mathrm{A}_{52}, \mathrm{~A}_{40}\right\}$ were frequented twice. Therefore, a higher order is taken for these frequent groups to obtain FSGs that do not contain frequent sets as in Table 5.

Table 5. FSGS for the TDS series after taking the higher order

After obtaining a series for a FSG free of frequencies, the $I f$-then rules for these sets have evaluated and Applied. The PSO function algorithm based on $w_{i}$ weights is for computing the value of defuzzification coefficients $X_{i}$. Table 6 explains the process of evaluating if-then rules and the specific results of weight $w_{i}$.

Table 6. Evaluation of $I f$-then rule with weights $w_{i}$ results of TDS data using PSO function

Table 6 shows that each fuzzy rule has corresponding weight $w_{i}$ values resulting from the application of the PSO function. To illustrate, we have the fuzzy rule (1) in Table 6 . Accordingly, weights are equal to $\left(\mathrm{w}_{1}=\right.$ $0.734, \mathrm{w}_{2}=0.1299$ ). The value of the linguistic variable in time $\mathrm{F}(\mathrm{t}-1)$ is equal to A17 and the value of the linguistic variable in time $\mathrm{F}(\mathrm{t}-2)$ equals to $\mathrm{A}_{32}$. Because this rule contains only two conditions, the number of
weights corresponding to this rule is only two. However, if the fuzzy rule contains three conditions, as in fuzzy rule 12 in the table, the number of corresponding weights will be three weights.
Throughout the values of the weights that have been obtained by using the PSO function, the formula of the defuzzification coefficient $X_{i}$ has been applied and used in the defuzzing process to obtain the predictive values time series as shown in Table 7.

Table 7. Predictive values of the TDS series after defuzzification

It is noted in Table 7 that the predictive values of time series data are close to actual values when using the high order fuzzy time series model and symbolized Fuzzypos

### 3.3. The proposed procedure in this study

Time series data for the $\operatorname{ARIMA}(3,1,3)$ model were taken as a new series as shown in Figure 7.

Figure 7. Time series data for the ARIMA model
The high order fuzzy time series model was combined to control the fluctuations of ARIMA series errors and to find a model with high accuracy and quality, by calculating the following: $\mathrm{AD}=2.1709$ and $\mathrm{ADR}=1.2867$, $\mathrm{U}=$ [372.1043, 761.0917]. The number of fuzzy sets is equal to $\mathrm{n}=151$. It's being able to define the fuzzy sets for new series (ARIMA) with 151 fuzzy sets. It can be defined by using TMF as shown in Table 8, which can be identified by using the TMF.

Table 8. Fuzzy sets of high order fuzzy model for ARIMA series

In the stage of defuzzification, FSGS elements have been established as in Table 10. It is clear that there are no frequencies in elements of FSGS.

Table 10. FSGS for the data of ARIMA series

| \# | FSGS | \# | FSGS | \# | FSGS | \# | FSGS | \# | FSGS |

The If-then rules have evaluated for the sets of Table 10. PSO function algorithm is applied to obtain the $w_{i}$ weights and calculate the value of the defuzzification coefficient $X_{i}$. Table 11 illustrates these steps:

Table 11. Evaluation of the $I f$-then rule and $w_{i}$ results of ARIMA data using PSO function

Table 11 shows that the number of fuzzy rules for all table results includes only two conditions. To illustrate, we have the fuzzy rule (1) in the table where weights are $\left(w_{1}=0.7487, w_{2}=0.143\right)$ if the value of the linguistic variable in time $F(t-1)$ is equal to $A_{19}$. The value of the linguistic variable in time $F(t-2)$ equals $A_{39}$. Through the values of weights obtained using the PSO function, the formula of the defuzzification coefficient $X_{i}$ is applied and used in the defuzzing process to obtain the predictive values of the time series as shown in Table 12.

Table 12. Predictive values to model the proposed procedure after defuzzification

Figure 8 shows the predictive values of the proposed procedure that can be symbolized ARIMA-Fuzzypso model.

Figure 8. Predictive values of the proposed ARIMA-Fuzzypso model

### 3.4. Comparison of results

The criteria of RMSE, MAE, and MAPE have calculated to compare the three models and find out the best model to predict the TDS in drinking water after calculating the predictive values of each method and comparing them with the actual values. Table 13 shows the results of the comparison.

Table 13. Comparison of prediction for the models

| No. | Model | Criteria | RMSE | MAE |
| :---: | :---: | :---: | :---: | :---: |
| 1 | ARIMA(3,1,3) | 51.131 | 39.658 | 7.910 |
| 2 | Fuzzypos | 48.357 | 37.250 | 6.862 |
| 3 | ARIMA-Fuzzypos | 46.016 | 35.402 | 6.128 |

It is clear from the table that the proposed ARIMA-Fuzzypos model has the lowest value of the criteria in Table 13. This indicates the efficiency of the proposal compared to the two models ARIMA $(3,1,3)$ and Fuzzypos . Therefore, it is considered the best model to predict the data of the studied phenomenon and it has ability to more predict with better performance.

## 4. Conclusions

1- When studying the B-J method for testing the dissolved solids for drinking water in Baghdad city, it was found that the ARIMA $(3,1,3)$ model is appropriate for the time series data which has the lowest value in the statistical criteria of RMSE, MAE, MAPE with its significant parameters.
2- There are no frequencies in FSGs elements in the proposal when calculating the high order fuzzy time series of the ARIMA series. In addition, all fuzzy rules included only two conditions and number of weights per rule is two. This did not appear when studying actual time series in high order fuzzy time series.
3- The use of the trapezoidal membership function in the fuzzification of time series data with the application of the PSO algorithm influenced the results of the predictive values. The fuzzy method has a mechanical ability to find solutions to different field's, which in turn affected the results of the proposal model by owning the lowest values in the comparison criteria.
4- Use the adaptation procedure between the high order fuzzy time series method and the B-J method as an alternative to classical statistical methods. It has given better predictive results if the B-J method was used only on the data. Thus, the best criteria of the proposed model appeared was ARIMA-Fuzzypos which improved the quality of the model with increased predictability, followed by the Fuzzypos model, while the latter is the ARIMA model.

## 5. Recommendations

1- Using the high order fuzzy time series to the dissolved solids data for drinking water in Baghdad city, due to its high accuracy in data processing and obtaining the best data predicate.
2 - Application of the ARIMA-Fuzzypos of proposed model for data dissolved solids for drinking water in the city of Baghdad, where it proved its accuracy and superiority.

3 - Use of high order fuzzy time series method for multivariate to be compared with the vector autoregressive moving average (VARMA) method by taking several chemical examinations of the drinking water pollution.
